Using $\LaTeX$ to Create Documents

I. M. Student

January 12, 2004

Abstract

This document extends a previous paper on creating $\LaTeX$ documents. Examples are provided within the text of the paper, but the reader can also view the source code for further clarity. This paper was designed to create a web page version to post on the Internet.

1 Introduction

$\LaTeX$ is a text formatting program that is extensively used to produce scientific journals, textbooks, and many other publications. The software is able to take irregular blocks of text with embedded commands, and assemble a device independent file that can be displayed on a computer screen or sent to a printer.

Similar to HTML tags used for the World Wide Web, $\LaTeX$ commands direct the program to produce a formatted document including graphics. Some of the formatting may seem more difficult than HTML, but the richness available in $\LaTeX$ is amazing including mathematical symbols and even a separate tag for software’s own name ($\LaTeX$).

As of now, $\LaTeX$ remains a standard for document presentation in many scientific communities.

2 Some $\LaTeX$ Basics

There are some basic principles of $\LaTeX$ that can help a person organize a research paper. These will be described in more detail in each subsection below with code examples for reference.

2.1 Document Header or Preamble

The preamble of a $\LaTeX$ document contains a number of global parameters that will control the entire document. It is similar to a Cascading Style Sheet in HTML. By the way, here’s an image (converted from jpeg to eps: convert image.jpeg image.eps)
